1. Introduction

It is often observed that phosphors doped with \( \text{Eu}^{2+} \) show rather intense broad photoluminescence (PL) bands with a real short decay time of hundreds of nanoseconds. The \( \text{Eu}^{2+} \) emission of many phosphor hosts has high enough intensity to find important applications, e.g. in fluorescent lamps and plasma displays [1-5]. An important class of phosphors doped with \( \text{Eu}^{2+} \) ions is based on alkaline earth aluminates [6]. In 1983, Van Kemenade and Hoeks reported that \( \text{Sr}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) phosphor had a higher quantum efficiency and better long persistence properties than those of traditional aluminate and sulphide phosphors. There are some articles based on the long afterglow of \( \text{Sr}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) phosphor [7-10]. However, there is no report in the literature on the existence and the luminescence properties of \( \text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) compound.

In the present work, we characterized \( \text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) phosphor which was prepared by using traditional solid state reaction method. The photoluminescence and thermoluminescence properties and long lasting phosphorescence mechanism of this phosphor were investigated systematically.

2. Experimental

2.1. Synthesis

The \( \text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) phosphor was prepared by solid-state reaction method involving \( \text{BaCO}_3, \text{Al(OH)}_3, \text{Eu}_2\text{O}_3 \) and \( \text{Dy}_2\text{O}_3 \) as the starting materials. A small amount of \( \text{H}_3\text{BO}_3 \) was added to the mixture as a flux. We weighed the components of the powder as it is in the nominal composition of \( 4\text{BaO}•(7-x)\text{Al}_2\text{O}_3•x\text{B}_2\text{O}_3 \) with 1% \( \text{Eu}_2\text{O}_3 \) and 2% \( \text{Dy}_2\text{O}_3 \) and thoroughly mixed and ground it with a ball mill. The mixed powder was placed into a platinum-lined boat and prefired at 1000 °C for 4 h for the initial decomposition reaction. Then, the powder was reground and sintered at 1300 °C for 7 h in reducing atmosphere (\( \text{N}_2, 90\% + \text{H}_2, 10\% \)). The sintered powder was grounded again and washed by using boiling acetic acid solution to remove amorphous barium borate phases.

2.2. Instrumentation

The structural phase identification of products were carried out by X-ray powder diffraction (XRD) [Bruker, AXS, East Cheryl Parkway, USA] with CuKα (\( \lambda=1.54\text{ Å} \)) radiation. Infrared spectrum (FT-IR) was recorded on a FT-IR Spectrometer (Mattson Satellite 3000, Thermo Electron Corporation, Erlangen, Germany) in the range of 4000-400 cm⁻¹ by dispersing the sample in anhydrous KBr pellets. A TG/DTA combined system [Shimadzu DTG-60H, Tokyo, Japan] was used to determine the reaction conditions in the temperature range of 25-1450 °C under inert \( \text{N}_2 \) atmosphere with flow rate of 10 mL/min. The diffuse reflectance measurement was carried out by using UV-Vis Spectrophotometer (Varian, Cary 100 Bio, Victoria, Australia) with DRA-CA-301 Diffuse Reflectance Accessory at room temperature (RT) in the wavelength range of 200-800 nm. Photoluminescence (PL) spectra were obtained at RT by using a Fluorescence Spectrophotometer (Warian, Cary Eclipse, Victoria, Australia). The thermo luminescence (TL) glow curve of \( \text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+} \) was measured by using a TL reader (Harshaw-QS 3500, Erlangen, Germany) at linear
heating rate of 1 °C/s after irradiation using a 90Sr/90Y β-source (2.2 MeV) at a dose rate of approximately 0.04 Gy/s at RT.

3. Results and Discussion

The DTA/TG curves of the starting materials are given in Figure 1. It seems that a weak endothermic peak between 30–214 °C with a 0.6% weight loss which belongs to the decomposition of boric acid. The three other endothermic peaks in DTA diagram at 240, 297 and 529 °C correspond to three different decomposition steps of Al(OH)3 in TG diagram with weight losses of 2.8%, 13.4% and 3.7%, respectively. The exothermic peak at 1000 °C corresponds to the decomposition of BaCO3 to BaO which reacts with Al2O3 and B2O3 to yield Ba4Al14O25.

The XRD patterns of Ba4Al14O25:Eu2+,Dy3+ calcined at 1300 °C are shown in Figure 2. The pattern can be indexed by using the WinxPow software [11]. The pattern can be indexed as a single phase having orthorhombic crystal system with Pnmm space group with unit cell parameters of 

\[ a = 18.200(6) \text{ Å}, \ b = 16.923(6) \text{ Å}, \ c = 5.131(21) \text{ Å} \] 

and with a volume of \( V = 1580.3(9) \text{ Å}^3 \), \( Z = 8 \). Ba4Al14O25 has the same crystall structure as Sr4Al14O25 which has a chain structure made of AlO6 octahedra, but strontium ions are sited in the cavities of the AlO4 tetrahedra [12].

The Infrared (FT-IR) Spectrum of Ba4Al14O25:Eu2+,Dy3+ phase is shown in Figure 3. The band which is observed in the infrared spectrum can be attributed to symmetric stretching at \( \gamma_{(Al-O)} = 688 \text{ cm}^{-1} \), symmetric bending \( \delta_{(O-Al-O)} = 495 \text{ cm}^{-1} \), antisymmetric stretching \( \gamma_{(Al-O)} = 770-990 \text{ cm}^{-1} \) and antisymmetric bending \( \delta_{(O-Al-O)} = 520-678 \text{ cm}^{-1} \) of AlO4 groups in Ba4Al14O25. The absorption band at 1050 cm\(^{-1}\) is assigned to B-O stretching vibration of tetrahedral BO4 units.

This indicates the presence of substitutional boron in AlO4 framework as Ba4Al14-xBxO25. When B2O3 was added as a flux, B2O3 took place in the formation of structural units by breaking off the O-Al-O-Al-O bonds in the aluminite framework and forms O-Al-O-B-O bonds [13].

The diffuse reflectance spectra of undoped Ba4Al14O25 is given in Figure 4. The broad band observed around 254 nm is due to the absorption across the band gap of the host matrix.

The diffuse reflectance spectra of the undoped Ba4Al14O25 was transformed by performing the Kubelka-Munk transformation of the measured reflectance according to the following equation:

\[ K = \frac{(1-R)^2}{2R} = F(R) \]
where $K$ is reflectance transformed according to Kubelka-Munk, $R$ is reflectancy (%), and $F(R)$ is the so-called remission or Kubelka-Munk function \[14-15\].

It is well known that the band gap $E_g$ and the absorption coefficient $\alpha$ are related as in following equation;

$$\alpha h\nu = A (h\nu - E_g)^{1/2} \quad (2)$$

where $A$ is a constant \[16-19\]. If the compound scatters in a perfectly diffuse manner, $K$ becomes equal to $2\alpha$. In this case, we can use the following expression;

$$[F(R)h\nu]^2 = A (h\nu - E_g) \quad (3)$$

The band gap $E_g$ of a powdered sample can be obtained easily from the $[F(R)h\nu]^2$ versus $h\nu$ plot.

The $[F(R)h\nu]^2$ versus $h\nu$ graph of $\text{Ba}_4\text{Al}_{14}\text{O}_{25}$ is presented in Figure 5. The band gap energy is obtained by extrapolating the straight portion of the curve to the $h\nu$ axis. The band gap value thus obtained turned out to be 4.72 eV.

The photoluminescence curves of undoped host phase, $\text{Ba}_4\text{Al}_{14}\text{O}_{25}$ and doped phase, $\text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+}$ are shown in Figure 6 and 7, respectively. The host phase shows red emission that has short lifetime, under 254 nm UV lamp. After excitation of undoped phase at 257 nm, it reveals two emission bands; one of them is a sharp band at 520 nm and the other one is a broad band in the range of 650-850 nm. The broad band emission of the host is probably due to the intrinsic defect in the host material. It is known that the crystallization process and the flux added can cause defects, which trap electrons and holes \[20\].

The emission spectrum of $\text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+}$ shows two broad bands around 520 nm with a shoulder at 496 nm and 650-850 nm range after excitation by 257 nm. The same results are obtained in the absence of rare-earth activators ($\text{Eu}^{2+}$ and $\text{Dy}^{3+}$). But, the $\text{Eu}^{2+}$ and $\text{Dy}^{3+}$ co-doped phosphor shows blue emission with long lasting phosphorescence. It is known that the emission of Eu$^{2+}$ ion in the crystalline phase generally shows a broad emission band due to $4f^5d^{10} \rightarrow 4f^7$ transition, on the other hand Eu$^{2+}$ ion gives a series of typical emission lines in the spectral region of 570-750 nm which correspond to $^2D_{5/2} \rightarrow {}^2F_{j}$ ($j=0-4$) transitions. It can be seen in Figure 7 that there is a broad band around 520 nm with a shoulder at 496 nm. The blue-green emission can be attributed to the interaction between the host crystal lattice and activator ions $\text{Eu}^{2+}$. The emission band at 520 nm observed in $\text{Ba}_4\text{Al}_{14}\text{O}_{25}$ host matrix and $\text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+}$ phosphor indicate that the emission is due to the native defect in the host crystal such as cation or anion vacancies. These traps in the doped phase may be created during the process of the incorporation of the activator (Eu) and co-activator (Dy) atoms. It must be mentioned that the intensity of the emission band at 520 nm of doped phase increased compared to the undoped phases. On the other hand, the band intensity between 650-850 nm of the doped phase decreased relative to the undoped phases.

The afterglow decay curve of $\text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+}$ phosphor is shown in Figure 8. The afterglow decay curve was measured by 496 nm emission wavelength intensity. The afterglow decay time had been analyzed by a curve fitting technique based on the following multiple equation:

$$I = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2) + A_3 \exp(-t/\tau_3) \quad (4)$$

where $I$ is phosphorescence intensity, $A_1$, $A_2$, and $A_3$ are constants, $t$ is the time, $\tau_1$, $\tau_2$, and $\tau_3$ are afterglow decay times for the exponential components, respectively \[21-22\]. Using the fitting function provided by ORIGIN61 software, the calculated afterglow decay times for the mentioned compounds were found as $\tau_1=9.60$ min, $\tau_2=12.06$ min and $\tau_3=15.19$ min, respectively. We can conclude that $4f^5d^{10} \rightarrow 4f^7$ transition in $\text{Ba}_4\text{Al}_{14}\text{O}_{25}:\text{Eu}^{2+},\text{Dy}^{3+}$ phosphor corresponds to a long afterglow which is caused by the energy processes between traps and activators, in this case Eu$^{2+}$ and Dy$^{3+}$. The phosphor exhibits a long afterglow over 5 h which is recognizable to the naked eye in the dark after the exciting source is removed.
Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ phosphor after irradiating the sample for 5 a bad fit. Figure 9 shows one of the analyzed glow curves of fit is good, between 2.5% and 3.5% it is a fair fit, and known that if the FOM values are between 0.0% and 2.5% the study. The recorded glow curve of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ was approximate solution of the general-order kinetics of the TL; TL glow curves were analyzed by using the following kinetic parameters can be easily obtained. In this program, the number of glow peaks present in the glow curve and their glow curves were analyzed by this program, the information on first analyzed using a curve fitting program [23]. When the glow curves of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ consists of several overlapping glow peaks. When more than one glow peak is present in a glow curve, there are essentially two ways to obtain these parameters: the first is to isolate each individual TL peak from the others using partial thermal annealing treatment and the other one is to make a complete glow curve overlying glow peaks. When one of the glow peaks is highly isolated from the others, the peak shape method is a suitable method to determine the kinetic parameters. In this respect, the peak 1 is highly isolated from the others and therefore in addition to the deconvolution method, the data of glow curves were also used to determine the kinetic parameters of peak 1 by the peak shape method. This method is based on the shape and full-width at half maximum (FWHM = T₂−T₁) of a single glow peak and the values of trap depth were determined by the modified peak shape method of Chen [26]. According to this method, the kinetic order of a single glow peak is easily obtained by means of the geometric factor {μₙ = (T₂−Tₚ)/(T₂−T₁)} and μₙ changes with the order of kinetics from ≈ 0.42 to ≈ 0.52, where these two limits correspond to first- and second-order kinetics, respectively. The trap depth E is calculated from the peak parameters by the following equations [23,26,27]:

\[ E \tau = \frac{1.51 + 3(\mu_G - 0.42)kT}{\tau} \left[ \frac{kT_m}{\tau} \right]^{(\mu_G - 0.42)kT} \]

where \( n_0 (\text{m}^3) \) is the concentration of trapped electrons at \( t = 0 \), \( T \) (K) is the absolute temperature, \( k \) (eV K⁻¹) is Boltzmann’s constant, \( s \) (s⁻¹) is frequency factor, \( \beta \) (K/s) is heating rate, \( b \) is the kinetic order, and \( E \) (eV) is the activation energy (trap depth). The goodness of fitting for all of the measured glow curves was tested using the figure of merit (FOM) [24-25]. It is known that if the FOM values are between 0.0% and 2.5% the fit is good, between 2.5% and 3.5% it is a fair fit, and >3.5% it is a bad fit. Figure 9 shows one of the analyzed glow curves of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ phosphor after irradiating the sample for 5 min (>12 GY) by β-rays. As can be seen clearly, the TL glow curves of this phosphor exhibit three TL glow peaks at about 50, 140 and 220 °C when heated at a constant heating rate of 1 °C/s. The obtained kinetic parameters by this method were given in the inset of Figure 9.

\[ n_0 = \frac{E}{kT_m} \exp (-\frac{E}{kT_m}) \left( 1 + (b - 1) \frac{2kT_m}{E} \right)^{-1} \]

Figure 8. Decay curve of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ phosphor.

Figure 9. An analyzed glow curve of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ obtained at a heating rate of 1 °C/s following β-ray exposure at room temperature (D=12 Gy). The open circles represent the experimental points, the full curve is the global fitting and broken curves represent fitted individual glow peaks.

As mentioned previously, if one glow peak is highly isolated from the others, the peak shape method is a suitable method to determine the kinetic parameters. In this respect, the peak 1 is highly isolated from the others and therefore in addition to the deconvolution method, the data of glow curves were also used to determine the kinetic parameters of peak 1 by the peak shape method. This method is based on the shape and full-width at half maximum (FWHM = T₂−T₁) of a single glow peak and the values of trap depth were determined by the modified peak shape method of Chen [26]. According to this method, the kinetic order of a single glow peak is easily obtained by means of the geometric factor {μₙ = (T₂−Tₚ)/(T₂−T₁)} and μₙ changes with the order of kinetics from ≈ 0.42 to ≈ 0.52, where these two limits correspond to first- and second-order kinetics, respectively. The trap depth E is calculated from the peak parameters by the following equations [23,26,27]:

\[ E \tau = \frac{1.51 + 3(\mu_G - 0.42)kT}{\tau} \left[ \frac{kT_m}{\tau} \right]^{(\mu_G - 0.42)kT} \]

where \( T_m \) is the peak temperature, \( \omega = T_m / T_1 \) is the full width at half-maximum, \( \delta = T_2 - T_m \) is the half width on the high temperature side of the maximum, and \( \mu_G/\omega \) is the geometric factor (peak-shape parameter). After determination of the trap depth and the order of kinetics, the frequency factor \( s \), in general, can be estimated using the relation

\[ s = \frac{kT_m^2}{\beta E} \exp (-\frac{E}{kT_m}) \left( 1 + (b - 1) \frac{2kT_m}{E} \right)^{-1} \]
The calculated kinetic parameters of peak 1 of Ba₄Al₁₄O₂₅:Eu²⁺,Dy³⁺ phosphor by the peak shape method are given in Table 1.

It is obvious that the higher the trap concentration the longer the afterglow because of the capturing of more free electrons that are excited by UV or ionizing irradiation. Moreover, another important parameter for a long lasting phosphor is to produce a suitable trap depth within the host. If the trap depth is too low, the electrons in the trap can return to the energy level of the excited states, thus resulting in a short afterglow lifetime. On the other hand, if the trap depth is too deep, the transition probability of electrons in the traps to the energy level of the excited state easily, thus resulting in a short afterglow over 5 h. Also, long afterglowing mechanism was discussed based on the Dorenbos model. If the phosphor is excited by UV light, the electrons escape from Eu²⁺ to the conduction band of Ba₄Al₁₄O₂₅ and Eu²⁺ will be converted to Eu³⁺. The escaped electrons are trapped by Dy³⁺ to create Dy²⁺. After the excitation, if the excitation source is removed, a slow thermal release of the electrons followed by re-trapping on Eu and thus creating a 4F⁵d¹→4F⁷ emission which causes a long persistent luminescence.
